meta_test_gitignore_precommit_audit.sh — companion guide

Revision: 1 **Last modified:** 2026-06-14T00:00:00Z

Overview

Paired §1.1 mutation proof for the CM-GITIGNORE-PRECOMMIT-AUDIT gate in `scripts/pre_build_verification.sh`. A gate without a paired mutation is itself a Constitution violation: this harness PROVES the gate is not a bluff (§1.1 / §11.4.30) by introducing a real violation of every forbidden class and asserting the gate flips to FAIL, then removing it and asserting PASS.

Prerequisites

- `bash`, `git`, `grep` on PATH.

Usage

```
bash scripts/testing/meta_test_gitignore_precommit_audit.sh
```

Exit codes: 0 gate proven sound · 1 gate is a bluff on ≥ 1 class · 2 harness error.

Internal behaviour

Builds a disposable, COMPLIANT git repo under `mktemp` (legit source + anchoring `.gitignore` + allow-listed `.env.example`) and points the gate at it via `PBV_REPO_ROOT`. The real project working tree is NEVER mutated; the tmp dir is removed on every exit path via a `trap`. Mutations exercised:

1. track `build/api-server` (declared build output) → FAIL → restore → PASS
2. track root `api-server` binary (anchoring regression) → FAIL → restore → PASS

3. track real `.env` secret file → FAIL → restore → PASS
4. track `api_keys.json` → FAIL → restore → PASS
5. negative: allow-listed `.env.example` stays PASS (no false positive)

Edge cases

- Uses `git add -f` against the disposable repo to stage files its own `.gitignore` would normally exclude — that is intentional: the test simulates the failure mode where a forbidden file slips into version control despite the ignore line.

Related scripts

- `scripts/pre_build_verification.sh` — the gate under test.

Last verified: 2026-06-14 (META-TEST RESULT: PASS).
